4.5.4.2 vtss_mem_flags_t

enum vtss_mem_flags_t

Memory allocation flags.

The VTSS API asks the application to allocate dynamic memory for its internal structures through calls to VTSS OS MALLOC().

The application should normally just associate this with a call to malloc() or kmalloc() depending on the OS and the runtime model (API running in Kernel or User space).

However, on some OSs, it's required to allocate specially if the memory is going to be associated with DMA, hence the VTSS_MEM_FLAGS_DMA enumeration.

Also, to be able to support warm restart, another enumeration, VTSS_MEM_FLAGS_PERSIST, tells the application to allocate the memory in a part of RAM that won't be affected by a subsequent boot.

VTSS_OS_MALLOC() must not block or make waiting points if called with flags != VTSS_MEM_FLAGS_NONE.

Each of the enumerations are ORed together to form the final flags that are used in a call to VTSS_OS_MALLOC().

The same set of flags are used in calls to VTSS OS FREE().

Enumerator

VTSS_MEM_FLAGS_NONE	Allocate normally according to runtime model (User or Kernel space).
VTSS_MEM_FLAGS_DMA	Allocate memory that can be used with a DMA.
VTSS_MEM_FLAGS_PERSIST	Allocate memory that will survive a warm restart.

Set an external hw nanosec read function.

Parameters

```
cb pointer to callback function
```

4.19.5.14 vtss_debug_reg_check_set()

Enable or disable register access checking.

When enabled, every call to the register read/write callouts (init_conf.reg_read()/write()) will be verified for success. This will slow-down execution, so it is recommended only to use this feature in dedicated debug builds.

In multi-chip targets, only chip number 0 will be verified.

The number of calls will be reference counted, according to the following rules: 1) Calls with enable = FALSE will increase the reference count. 2) Calls with enable = TRUE will decrease the reference count, which cannot go lower than 0. The reference count is initialized to 1 at API instantiation, effectively disabling register access checking. A reference count of 0 enables the feature.

Error indications get printed with a call to VTSS_EG(VTSS_TRACE_GROUP_REG_CHECK, ...), which will request to be interrupt/scheduler disabled tolerant.

Notice that this feature may not be available on all platforms.

This feature will not work if the API is instantiated more than once, since it uses the default instance to find its state.

Parameters

inst	[IN] Target instance reference.
enable	[IN] Enable or disable register access checking (ref. counted).

Returns

Return code.

4.25.2.16 VTSS_OS_REORDER_BARRIER

```
#define VTSS_OS_REORDER_BARRIER() HAL_REORDER_BARRIER()
```

The compiler may swap instructions to optimize performance of the final code (size- or speed-wise). When configuration of hardware is involved, it may not always be valid to swap two statements. Consider for instance the following two writes to two FDMA registers: Write the source address to the FDMA Enable the FDMA. To the compiler, these two writes can be executed in any order and still semantically yield the correct result, had it been normal RAM they were written to. But since they are written to actual hardware, it is crucial that they are executed in the correct order. The VTSS_OS_REORDER_BARRIER() macro should implement code that ensures that the compiler doesn't optimize across the barrier.

Definition at line 173 of file vtss_os_ecos.h.

4.25.2.17 VTSS_OS_COMPILER_ATTRIBUTE_ALIGNED

In some special cases, it is of utmost importance that a certain variable has a certain memory alignment. Applications for this is e.g. placing variables on cache-line boundaries.

4.25.2.24 VTSS_OS_SCHEDULER_FLAGS

```
#define VTSS_OS_SCHEDULER_FLAGS cyg_uint32 __attribute__((unused))
```

VTSS_OS_SCHEDULER_FLAGS VTSS_OS_SCHEDULER_LOCK(flags) VTSS_OS_SCHEDULER_UNLOCK(flags) These functions are called by API code that consists of a user-level part and a deferred interrupt handler part. Only the user-level part will call the VTSS_OS_SCHEDULER_LOCK()/UNLOCK() functions, since it is assumed that the deferred interrupt handler will have atomic access throughout its execution. Each module within the API that contains such functionality will have an option to call either the VTSS_OS_SCHEDULER_(UN)LOCK() functions or the VTSS_OS_INTERRUPT_DISABLE()/RESTORE() functions. The attribute((unused)) ensures that we don't get compiler warnings.

```
#define VTSS_OS_INTERRUPT_FLAGS NOT_NEEDED
```

VTSS_OS_INTERRUPT_FLAGS VTSS_OS_INTERRUPT_DISABLE(flags) VTSS_OS_INTERRUPT_RESTORE(flags) These functions are called by API code that consists of a user-level part and an interrupt handler part executing directly in interrupt context. Only the user-level part will call the VTSS_OS_INTERRUPT_DISABLE()/RESTORE() functions, since it is assumed that the interrupt handler will have atomic access throughout its execution. Each module within the API that contains such functionality will have an option to call either the VTSS_OS_SCHED ∪ ULER_(UN)LOCK() functions or the VTSS_OS_INTERRUPT_DISABLE()/RESTORE() functions. Not needed in eCos, since all interrupt handlers will be called in deferred context.

Request OS to allocate size bytes of memory.

The first argument is the number of bytes that must be allocated. Type is size_t.

The second argument is a mask of flags that the implementation must obey. Type is vtss_mem_flags_t.

The returned pointer should be at least 8-byte aligned, to make it suitable for a struct.

Request OS to free memory previously allocated with VTSS_OS_MALLOC().

The first argument is the pointer previously obtained with a call to VTSS_OS_MALLOC(). Type is void *.

The second argument is a mask of flags identical to those passed to VTSS_OS_MALLOC() when the memory was requested.
